

Methodology (System wide operational capacity is set by the design/as built capacity of the system with a starting pressure within 10# of MAOP and a minimum delivery pressure of 650#. This figure is then reduced by any maintenance impacts for the day or period in question. Operationally available system capacity is then defined as the adjusted operational system capacity netted against the confirmed contractual nominations. Point capacity is set by the meter maximum as determined by the measurement group. The operationally available point capacity is defined as the greater of the meter maximum less contractual nominations at the point or the operationally available system capacity.)
